

INCORRECT ASSEMBLY

- CAUSE Tightening sequence incorrect. Insufficient tightening torque used
- **EFFECT** Vibration particularly on initial brake applications
- **REMEDY** Replace the discs and adhere to both correct fitment sequence and manufacturer's recommended torque settings

APPEARANCE Hub contact surface is detached or distorted

- **CAUSE** Excessive tightening and failure to observe manufacturer's
- recommended torque and sequence during tightening
- **EFFECT** Detachment of disc contact surface. Complete brake failure **REMEDY** Full inspection of braking system and associated components. Replace any failed components and fit new discs observing manufacturer's recommended torgue and sequence during tightening

APPEARANCE Blue spots, darker colour of some disc areas. Evidence of localised overheating

CAUSE Excessive hub run-out. Uneven disc-to-pad contact generates excessive oscillation which in turn leads to localised heat generation – subsequently discolouration (blueing)

EFFECT Progressively increasing noise and vibration

REMEDY Correct the wheel hub run-out and ensure that this falls within the correct tolerances

APPEARANCE Distortion of the hub contact surface and/or cracking around it CAUSE Overly severe tightening torque used on the positioning screw

- **EFFECT** Vibrations experienced from initial brake applications onwards
- **REMEDY** Replace the discs avoiding excessive tightening torque.
- Positioning screws are only intended to ensure that discs are positioned correctly

APPEARANCE Dirt and/or rust on hub surface

- **CAUSE** Contamination on the hub surface can lead to misalignment during mounting leading to irregular contact between pad and disc surfaces and uneven wear of the disc
- **EFFECT** Disc Thickness Variation which leads to oscillation of the disc surface resulting in noise and vibration. The effect becomes progressively greater with use
- **REMEDY** Remove the disc and carefully clean the surfaces of wheel hub and disc, eliminating rust and other debris. Check that the support surface is neither distorted nor damaged. Replace discs observing manufacturer's recommended torque and sequence during tightening

brake pads and discs as necessary

TROUBLE TRACER – BRAKE DISCS

APPEARANCE Detachment of the disc hat from the braking surface

- **CAUSE** Mechanical stress through misalignment. Incorrect assembly or positioning of the caliper and disc results in ongoing asymmetrical wear of the braking surface, eventually causing
- EFFECT Initially loud noise and vibration during braking with complete mechanical failure after detachment
- **REMEDY** Full inspection of braking system and associated components. Replace any failed components and fit new discs observing manufacturer's recommended torque and sequence during tightening. Before fitting discs check the alignment and assembly of the caliper body on the axle

used by loose abrasive particles between In debris may enter from outside the brake or from poorly mixed friction material

d normal running, and lower brake ed braking contact surface

MISUSE/THERMAL DAMAGE

APPEARANCE Radial fractures/blue spots corresponding to the venting frames **CAUSE** The blue spots are symptomatic of rising cracks. These are caused by metallurgical change in the surface material making it hard and brittle. This is typical of overloading the brakes beyond

normal design limits. This could result from intensive or unusual brake use e.g. aggressive driving or excessive payload **EFFECT** Brake fade/reduced brake performance, noise, vibrations

SOLUTION Replace the discs, avoid abuse of the brake system and make more efficient use of the engine/gears to aid speed reduction

APPEARANCE Discs show colouring of varying intensity and shades (blue, violet golden)

- **CAUSE** Poor bedding-in. It is normal on new installations to experience slight variations on the surface between the pad and disc. If not properly bedded, the surfaces where friction occurs become overheated leading to a metallurgical change on the friction surface
- **EFFECT** Poor brake efficiency due to decreased friction. Vibrations can occur which may worsen over the life of the pad and disc
- **SOLUTION** Replace the discs and respect the correct bedding procedure, i.e. moderate use of the brake during the first 200 kilometres

- ion glazing and/or dark spots
- is have transferred to the disc surface.
- e poor quality brake pads have been fitted efficiency and hard pedal
- brake pads with friction material suited

- e pad is in constant contact with the ear down to the metal backing plate. ntact with the backing plate becomes ther side of the disc and the other pad
- vibration and low braking efficiency. ing action with vehicle pulling to one side ked, replaced or repaired. Replace

ABNORMAL WEAR

APPEARANCE Excessive wear. Disc thickness is lower than manufacturer's recommended 'Minimum Thickness'

CAUSE Discs were not checked regularly or changed at the correct point

EFFECT Performance decrease, vibration and excessive noise while braking **SOLUTION** Full inspection of braking system and associated components. Replace any failed components and fit new discs observing manufacturer's recommended torque and sequence during tightening. Ensure future checking and periodic maintenance

- **APPEARANCE** Disc heavily worn with surface grooves **CAUSE** Excessive or complete brake pad wear results the brake pad backing plate contacting the disc (metal to metal) damaging the disc surface
 - **EFFECT** Very low braking efficiency/increased stopping distances and grinding noise
 - SOLUTION Replace discs and pads. Where applicable, confirm the pad wear warning indicator circuit is working correctly

APPEARANCE Deep grooving between hat and disc surface

- **CAUSE** Excessive pad and disc wear may lead to movement of the backing plate within the caliper. In this case, the backplate of the worn pad has come loose from its seat within the caliper causing grooving between hat and disc surface
- **EFFECT** Very low braking efficiency with a long pedal stroke and heavy noise
- SOLUTION Replace discs and pads. Check and, if necessary, repair the caliper
